Abstract

In this work we introduce a new succinct variant of the word problem in a finitely generated group G , which we call the power word problem: the input word may contain powers p^x , where p is a finite word over generators of G and x is a binary encoded integer. The power word problem is a restriction of the compressed word problem, where the input word is represented by a straight-line program (i.e., an algebraic circuit over G). The main result of the paper states that the power word problem for a finitely generated free group F is AC^0 -Turing-reducible to the word problem for F . Moreover, the following hardness result is shown: For a wreath product $G \wr \mathbb{Z}$, where G is either free of rank at least two or finite non-solvable, the power word problem is complete for $coNP$. This contrasts with the situation where G is abelian: then the power word problem is shown to be in TC^0 .

1 Introduction

Algorithmic problems in group theory have a long tradition, going back to the work of Dehn from 1911 [9]. One of the fundamental group theoretic decision problems introduced by Dehn is the *word problem* for a finitely generated group G (with a fixed finite generating set Σ): does a given word $w \in \Sigma^*$ evaluate to the group identity? Novikov [35] and Boone [8] independently proved in the 1950's the existence of finitely presented groups with undecidable word problem. On the positive side, in many important classes of groups the word problem is decidable, and in many cases also the computational complexity is quite low. Famous examples are finitely generated linear groups, where the word problem belongs to deterministic logarithmic space (L for short) [22] and hyperbolic groups where the word problem can be solved in linear time [17] as well as in LOGCFL [23].

In recent years, also compressed versions of group theoretical decision problems, where input words are represented in a succinct form, have attracted attention. One such succinct representation are so-called straight-line programs, which are context-free grammars that produce exactly one word. The size of such a grammar can be much smaller than the word it produces. For instance, the word a^n can be produced by a straight-line program of size $\mathcal{O}(\log n)$. For the *compressed word problem* for the group G the input consists of a straight-line program that produces a word w over the generators of G and it is asked

23:2 The power word problem

44 whether w evaluates to the identity element of G . This problem is a reformulation of the
 45 circuit evaluation problem for G . The compressed word problem naturally appears when
 46 one tries to solve the word problem in automorphism groups or semidirect products [25,
 47 Section 4.2]. For the following classes of groups, the compressed word problem is known to
 48 be solvable in polynomial time: finite groups (where the compressed word problem is either
 49 P-complete or in NC^2 [6]), finitely generated nilpotent groups [20] (where the complexity is
 50 even in NC^2), hyperbolic groups [18] (in particular, free groups), and virtually special groups
 51 (i.e. finite extensions of subgroups of right-angled Artin groups) [25]. The latter class covers
 52 for instance Coxeter groups, one-relator groups with torsion, fully residually free groups and
 53 fundamental groups of hyperbolic 3-manifolds. For finitely generated linear groups there
 54 is still a randomized polynomial time algorithm for the compressed word problem [26, 25].
 55 Simple examples of groups where the compressed word problem is intractable are wreath
 56 products $G \wr \mathbb{Z}$ with G a non-abelian group: for every such group the compressed word
 57 problem is coNP -hard [25] (this includes for instance Thompson’s group F); on the other
 58 hand, if, in addition, G is finite, then the (ordinary) word problem for $G \wr \mathbb{Z}$ is in NC^1 [38].

59 In this paper, we study a natural variant of the compressed word problem, called
 60 the *power word problem*. An input for the power word problem for the group G is a
 61 tuple $(p_1, x_1, p_2, x_2, \dots, p_n, x_n)$ where every p_i is a word over the group generators and
 62 every x_i is a binary encoded integer (such a tuple is called a *power word*); the ques-
 63 tion is whether $p_1^{x_1} p_2^{x_2} \dots p_n^{x_n}$ evaluates to the group identity of G . From a power word
 64 $(p_1, x_1, p_2, x_2, \dots, p_n, x_n)$ one can easily (e.g. by an AC^0 -reduction) compute a straight-line
 65 program for the word $p_1^{x_1} p_2^{x_2} \dots p_n^{x_n}$. In this sense, the power word problem is at most
 66 as difficult as the compressed word problem. On the other hand, both power words and
 67 straight-line programs achieve exponential compression in the best case; so the additional
 68 difficulty of the the compressed word problem does not come from a higher compression rate
 69 but rather because straight-line programs can generate more “complex” words.

70 Our main results for the power word problem are the following; in each case we compare
 71 our results with the corresponding results for the compressed word problem:

- 72 ■ The power word problem for every finitely generated nilpotent group is in DLOGTIME -
 73 uniform TC^0 and hence has the same complexity as the word problem (or the problem of
 74 multiplying binary encoded integers). The proof is a straightforward adaption of a proof
 75 from [34]. There, the special case, where all words p_i in the input power word are single
 76 generators, was shown to be in DLOGTIME -uniform TC^0 . The compressed word problem
 77 for every finitely generated nilpotent group belongs to the class $\text{DET} \subseteq \text{NC}^2$ and is hard
 78 for the counting class C=L in case of a torsion-free nilpotent group [20].
- 79 ■ The power word problem for a finitely generated group G is NC^1 -many-one-reducible to
 80 the power word problem for any finite index subgroup of G . An analogous result holds
 81 for the compressed word problem as well [20].
- 82 ■ The power word problem for a finitely generated free group is AC^0 -Turing-reducible to
 83 the word problem for F_2 (the free group of rank two) and therefore belongs to L . In
 84 contrast, it was shown in [24] that the compressed word problem for a finitely generated
 85 free group of rank at least two is P-complete.
- 86 ■ The power word problem for a wreath product $G \wr \mathbb{Z}$ with G finitely generated abelian
 87 belongs to DLOGTIME -uniform TC^0 . For the compressed word problem for $G \wr \mathbb{Z}$ with G
 88 finitely generated abelian only the existence of a randomized polynomial time algorithm
 89 for the complement is known [21].
- 90 ■ The power word problem for the wreath products $F_2 \wr \mathbb{Z}$ and every wreath product $G \wr \mathbb{Z}$,
 91 where G is finite and non-solvable, is coNP -complete. For these groups this sharpens the

class of groups	POWERWP	COMPRESSEDWP	WP
nilpotent groups	TC^0	DET, C=L-hard [20]	TC^0 [36]
Grigorchuk group G	L^a	PSPACE	L [13, 30]

$G \wr \mathbb{Z}$ for G f.g. abelian	TC^0	coRP [21]	TC^0 [31]
$G \wr \mathbb{Z}$ for G finite non-solvable	coNP-complete	PSPACE, coNP-hard [25]	NC^1 [38]
$F_2 \wr \mathbb{Z}$	coNP-complete	PSPACE, coNP-hard [25]	L^b [38]
finite extension of a f.g. group H	NC^1 -many-one-reducible to POWERWP(H) (resp. COMPRESSEDWP(H) [20], resp. WP(H) [38])		

a) AC^0 -many-one-reducible to the word problem of G .

b) AC^0 -Turing-reducible to the word problem of F_2 .

■ **Table 1** Our results on the power word problem compared to previous results on the (compressed) word problem. Here WP stands for “word problem”.

92 corresponding coNP-hardness result for the compressed word problem [25].

93 ■ The power word problem for the Grigorchuk group is uAC^0 -many-one-reducible to the
 94 word problem. The word problem for the Grigorchuk group is in L [13, 30], which implies
 95 that the compressed word problem is in PSPACE.

96 Table 1 summarizes the above results. Due to space constraints we present only short proof
 97 skteches for our main theorems; proofs of all lemmas can be found in the full version [27].

98 **Related work.** Implicitly, (variants of) the power word problem have been studied before.
 99 In the commutative setting, Ge [14] has shown that one can verify in polynomial time an
 100 identity $\alpha_1^{x_1} \alpha_2^{x_2} \cdots \alpha_n^{x_n} = 1$, where the α_i are elements of an algebraic number field and the
 101 x_i are binary encoded integers.

102 Another problem related to the power word problem is the knapsack problem [12, 28, 32]
 103 for a finitely generated group G (with generating set Σ): for a given sequence of words
 104 $w, w_1, \dots, w_n \in \Sigma^*$, the question is whether there exist $x_1, \dots, x_n \in \mathbb{N}$ such that $w =$
 105 $w_1^{x_1} \cdots w_n^{x_n}$ holds in G . For many groups G one can show that if such $x_1, \dots, x_n \in \mathbb{N}$ exist,
 106 then there exist such numbers of size $2^{\text{poly}(N)}$, where $N = |w| + |w_1| + \cdots + |w_n|$ is the input
 107 length. This holds for instance for right-angled Artin groups (also known as graph groups).
 108 In this case, one nondeterministically guesses the binary encodings of numbers x_1, \dots, x_n and
 109 then verifies, using an algorithm for the power word problem, whether $w_1^{x_1} \cdots w_n^{x_n} w^{-1} = 1$
 110 holds. In this way, it was shown in [28] that for every right-angled Artin group the knapsack
 111 problem belongs to NP (using the fact that the compressed word problem and hence the
 112 power word problem for a right-angled Artin group belongs to P).

113 In [16], Gurevich and Schupp present a polynomial time algorithm for a compressed
 114 form of the subgroup membership problem for a free group F , where group elements are
 115 represented in the form $a_1^{x_1} a_2^{x_2} \cdots a_n^{x_n}$ with binary encoded integers x_i . The a_i must be
 116 standard generators of the free group F . This is the same input representation as in [34]
 117 and is more restrictive than our setting, where we allow powers of the form w^x for w an
 118 arbitrary word over the group generators (on the other hand, Gurevich and Schupp consider
 119 the subgroup membership problem, which is more general than the word problem).

2 Preliminaries

Words. An *alphabet* is a (finite or infinite) set Σ ; an element $a \in \Sigma$ is called a *letter*. The free monoid over Σ is denoted by Σ^* , its elements are called *words*. The multiplication of the monoid is concatenation of words. The identity element is the empty word 1. The length of a word w is denoted by $|w|$. If w, p, x, q are words such that $w = pxq$, then we call x a *factor* of w , p a *prefix* of w , and q a *suffix* of w . We write $v \leq_{\text{pref}} w$ (resp. $v <_{\text{pref}} w$) if v is a (strict) prefix of w and $v \leq_{\text{suff}} w$ (resp. $v <_{\text{suff}} w$) if v is a (strict) suffix of w .

String rewriting systems. Let Σ be an alphabet and $S \subseteq \Sigma^* \times \Sigma^*$ be a set of pairs, called a *string rewriting system*. We write $\ell \rightarrow r$ if $(\ell, r) \in S$. The corresponding *rewriting relation* \xrightarrow{S} over Σ^* is defined by: $u \xrightarrow{S} v$ if and only if there exist $\ell \rightarrow r \in S$ and words $s, t \in \Sigma^*$ such that $u = s\ell t$ and $v = srt$. We also say that u can be rewritten to v in one step. We write $u \xrightarrow[k]{S} v$ if u can be rewritten to v in exactly k steps, i.e., if there are u_0, \dots, u_k with $u = u_0$, $v = u_k$ and $u_i \xrightarrow{S} u_{i+1}$ for $0 \leq i \leq k-1$. We denote the transitive closure of \xrightarrow{S} by $\xrightarrow{+}{S} = \bigcup_{k \geq 1} \xrightarrow[k]{S}$ and the reflexive and transitive closure by $\xrightarrow{*}{S} = \bigcup_{k \geq 0} \xrightarrow[k]{S}$. Moreover \xleftrightarrow{S} is the reflexive, transitive, and symmetric closure of \xrightarrow{S} ; it is the smallest congruence containing S . The set of *irreducible word* with respect to S is $\text{IRR}(S) = \{w \in \Sigma^* \mid \text{there is no } v \text{ with } w \xrightarrow{S} v\}$.

Free groups. Let X be a set and $X^{-1} = \{a^{-1} \mid a \in X\}$ be a disjoint copy of X . We extend the mapping $a \mapsto a^{-1}$ to an involution without fixed points on $\Sigma = X \cup X^{-1}$ by $(a^{-1})^{-1} = a$ and finally to an involution without fixed points on Σ^* by $(a_1 a_2 \dots a_n)^{-1} = a_n^{-1} \dots a_2^{-1} a_1^{-1}$. For an integer $z < 0$ and $w \in \Sigma^*$ we write w^z for $(w^{-1})^{-z}$. The string rewriting system $S = \{aa^{-1} \rightarrow 1 \mid a \in \Sigma\}$ is strongly confluent and terminating meaning that for every word $w \in \Sigma^*$ there exists a unique word $\text{red}(w) \in \text{IRR}(S)$ with $w \xrightarrow{*}{S} \text{red}(w)$ (for precise definitions see e.g. [7, 19]). Words from $\text{IRR}(S)$ are called *freely reduced*. The system S defines the free group $F_X = \Sigma^*/S$ with basis X . More concretely, elements of F_X can be identified with freely reduced words, and the group product of $u, v \in \text{IRR}(S)$ is defined by $\text{red}(uv)$. With this definition $\text{red} : \Sigma^* \rightarrow F_X$ becomes a monoid homomorphism that commutes with the involution \cdot^{-1} : $\text{red}(w)^{-1} = \text{red}(w^{-1})$ for all words $w \in \Sigma^*$. If $|X| = 2$ then we write F_2 for F_X . It is known that for every countable set X , F_2 contains an isomorphic copy of F_X .

Finitely generated groups and the power word problem. A group G is called *finitely generated* if there exist a finite set X and a surjective group homomorphism $h : F_X \rightarrow G$. In this situation, the set $\Sigma = X \cup X^{-1}$ is called a finite (symmetric) generating set for G . For words $u, v \in \Sigma^*$ we usually say that $u = v$ in G or $u =_G v$ in case $h(\text{red}(u)) = h(\text{red}(v))$. The *word problem* for the finitely generated group G , $\text{WP}(G)$ for short, is defined as follows:

- input: a word $w \in \Sigma^*$.
- question: does $w =_G 1$ hold?

A *power word* (over Σ) is a tuple $(p_1, x_1, p_2, x_2, \dots, p_n, x_n)$ where $p_1, \dots, p_n \in \Sigma^*$ are words over the group generators (called the periods of the power word) and $x_1, \dots, x_n \in \mathbb{Z}$ are integers that are given in binary notation. Such a power word represents the word $p_1^{x_1} p_2^{x_2} \dots p_n^{x_n}$. Quite often, we will identify the power word $(p_1, x_1, p_2, x_2, \dots, p_n, x_n)$ with the word $p_1^{x_1} p_2^{x_2} \dots p_n^{x_n}$. Moreover, if $x_i = 1$, then we usually omit the exponent 1 in a power

161 word. The *power word problem* for the finitely generated group G , $\text{POWERWP}(G)$ for short,
 162 is defined as follows:

- 163 ■ input: a power word $(p_1, x_1, p_2, x_2, \dots, p_n, x_n)$.
- 164 ■ question: does $p_1^{x_1} p_2^{x_2} \dots p_n^{x_n} =_G 1$ hold?

165 Due to the binary encoded exponents, a power word can be seen as a succinct description
 166 of an ordinary word. Hence, a priori, the power word problem for a group G could be
 167 computationally more difficult than the word problem. We will see examples of groups G ,
 168 where $\text{POWERWP}(G)$ is indeed more difficult than $\text{WP}(G)$ (under standard assumptions
 169 from complexity theory), as well as examples of groups G , where $\text{POWERWP}(G)$ and $\text{WP}(G)$
 170 are equally difficult.

171 **Wreath products.** Let G and H be groups. Consider the direct sum $K = \bigoplus_{h \in H} G_h$,
 172 where G_h is a copy of G . We view K as the set $G^{(H)}$ of all mappings $f: H \rightarrow G$ such that
 173 $\text{supp}(f) := \{h \in H \mid f(h) \neq 1\}$ is finite, together with pointwise multiplication as the group
 174 operation. The set $\text{supp}(f) \subseteq H$ is called the *support* of f . The group H has a natural left
 175 action on $G^{(H)}$ given by $hf(a) = f(h^{-1}a)$, where $f \in G^{(H)}$ and $h, a \in H$. The corresponding
 176 semidirect product $G^{(H)} \rtimes H$ is the (restricted) *wreath product* $G \wr H$. In other words:

- 177 ■ Elements of $G \wr H$ are pairs (f, h) , where $h \in H$ and $f \in G^{(H)}$.
- 178 ■ The multiplication in $G \wr H$ is defined as follows: Let $(f_1, h_1), (f_2, h_2) \in G \wr H$. Then
 179 $(f_1, h_1)(f_2, h_2) = (f, h_1 h_2)$, where $f(a) = f_1(a) f_2(h_1^{-1}a)$.

180 **Complexity.** We assume that the reader is familiar with the complexity classes P, NP, and
 181 coNP and many-one reductions; see e.g. [2] for details. We use circuit complexity for classes
 182 below deterministic logspace (L for short).

183 A language $L \subseteq \{0, 1\}^*$ is AC^0 -Turing-reducible to $K \subseteq \{0, 1\}^*$ if there is a family of
 184 constant-depth, polynomial-size Boolean circuits with oracle gates for K deciding L . More
 185 precisely, $L \subseteq \{0, 1\}^*$ belongs to $\text{AC}^0(K)$ if there exists a family $(C_n)_{n \geq 0}$ of circuits which,
 186 apart from the input gates x_1, \dots, x_n are built up from *not*, *and*, *or*, and *oracle gates* for K
 187 (which output 1 if and only if their input is in K). All gates may have unbounded fan-in,
 188 but there is a polynomial bound on the number of gates and wires and a constant bound
 189 on the depth (length of a longest path from an input gate x_i to the output gate o). Finally,
 190 C_n accepts exactly the words from $L \cap \{0, 1\}^n$, i.e., if each input gate x_i receives the input
 191 $a_i \in \{0, 1\}$, then a distinguished output gate evaluates to 1 if and only if $a_1 a_2 \dots a_n \in L$.

192 In the following, we only consider DLOGTIME-uniform $\text{AC}^0(K)$ for which we write
 193 $\text{uAC}^0(K)$. DLOGTIME-uniform means that there is a deterministic Turing machine which
 194 decides in time $\mathcal{O}(\log n)$ on input of two gate numbers (given in binary) and the string 1^n
 195 whether there is a wire between the two gates in the n -input circuit and also computes the
 196 type of a given gate. For more details on these definitions we refer to [37]. If the languages
 197 K and L in the above definition of $\text{uAC}^0(K)$ are defined over a non-binary alphabet Σ , then
 198 one first has to fix a binary encoding of words over Σ .

199 The class uTC^0 is defined as $\text{uAC}^0(\text{MAJORITY})$ where MAJORITY is the problem to
 200 determine whether the input contains more 1s than 0s. The class NC^1 is the class of languages
 201 accepted by Boolean circuits of bounded fan-in and logarithmic depth. When talking about
 202 hardness for uTC^0 or NC^1 we use uAC^0 -Turing reductions unless stated otherwise. As a
 203 consequence of Barrington's theorem [3], we have $\text{NC}^1 = \text{uAC}^0(\text{WP}(A_5))$ where A_5 is the
 204 alternating group over 5 elements [37, Corollary 4.54]. Moreover, the word problem for any
 205 finite group G is in NC^1 . Robinson proved that the word problem for the free group F_2 is
 206 NC^1 -hard [36], i.e., $\text{NC}^1 \subseteq \text{uAC}^0(\text{WP}(F_2))$.

207 **3 Results**

208 In this section we state our (and prove the easy) results on the power word problem. Outlines
209 of the proofs of Theorems 2, 8 and 9 can be found in Sections 4 and 5, respectively.

210 ► **Theorem 1.** *If G is a finitely generated nilpotent group, then $\text{POWERWP}(G)$ is in uTC^0 .*

211 **Proof.** In [34], the so-called word problem with binary exponents was shown to be in uTC^0
212 for finitely generated nilpotent groups. We can apply the same techniques as in [34]: we
213 compute Mal'cev normal forms of all p_i [34, Theorem 5], then use the power polynomials
214 from [34, Lemma 2] to compute Mal'cev normal forms with binary exponents of all $p_i^{x_i}$.
215 Finally, we compute the Mal'cev normal form of $p_1^{x_1} \cdots p_n^{x_n}$ again using [34]. ◀

216 ► **Theorem 2.** *The power word problem for a finitely generated free group is AC^0 -Turing-
217 reducible to the word problem for the free group F_2 .*

218 Notice that if the free group has rank one, then the power word problem is in uTC^0 because
219 iterated addition is in uTC^0 .

220 ► **Remark 3.** If the input is of the form $(p_1, x_1, p_2, x_2, \dots, p_n, x_n)$ where all p_i are freely
221 reduced, then the reduction in Theorem 2 is a uTC^0 -many-one reduction.

222 ► **Remark 4.** One can consider variants of the power word problem, where the exponents are
223 not given in binary representation but in even more compact forms. *Power circuits* as defined
224 in [33] are such a representation that allow non-elementary compression for some integers.
225 The proof of Theorem 2 involves iterated addition and comparison of exponents. For power
226 circuits iterated addition is in uAC^0 (just putting the power circuits next to each other), but
227 comparison (even for equality) is P-complete [39]. Hence, the variant of the power word
228 problem, where exponents are encoded with power circuits is P-complete for free groups.

229 ► **Remark 5.** The proof of Theorem 2 can be easily generalized to free products. However, in
230 order to have a simpler presentation we only state and prove the result for free groups and
231 postpone the free product case to a future full version.

232 It is easy to see that the power word problem for every finite group belongs to NC^1 . The
233 following result generalizes this fact:

234 ► **Theorem 6.** *Let G be finitely generated and let $H \leq G$ have finite index. Then
235 $\text{POWERWP}(G)$ is NC^1 -many-one-reducible to $\text{POWERWP}(H)$.*

236 **Proof sketch.** W.l.o.g. we can assume that H is a finitely generated normal subgroup and
237 R is a finite set of representatives of $Q := G/H$ with $1 \in R$. As a first step we replace in
238 the input power word every $p_i^{x_i}$ by $h_i^{y_i} p_i^{z_i}$ where $x_i = y_i |Q| + z_i$, $0 \leq z_i < |Q|$ and h_i is a
239 word over the generators of H with $p_i^{|Q|} =_G h_i$. Moreover, we write $p_i^{z_i}$ as a word without
240 exponents. Using the conjugate collection process from [36, Theorem 5.2], the result can be
241 rewritten in the form hr where h is a power word in the subgroup H and $r \in R$. ◀

242 As an immediate consequence of Theorem 2, Theorem 6 and the NC^1 -hardness of the
243 word problem for F_2 [36, Theorem 6.3] we obtain:

244 ► **Corollary 7.** *The power word problem for every finitely generated virtually free group is
245 AC^0 -Turing-reducible to the word problem for the free group F_2 .*

246 ► **Theorem 8.** *For every finitely generated abelian group G , $\text{POWERWP}(G \wr \mathbb{Z})$ is in uTC^0 .*

247 ► **Theorem 9.** *Let G be either a finite non-solvable group or a finitely generated free group*
 248 *of rank at least two. Then $\text{POWERWP}(G \wr \mathbb{Z})$ is coNP-complete.*

249 ► **Theorem 10.** *The power word problem for the Grigorchuk group (as defined in [15] and*
 250 *also known as first Grigorchuk group) is uAC⁰-many-one-reducible to its word problem.*

251 Theorem 10 applies only if the generating set contains a neutral letter. Otherwise, the
 252 reduction is in uTC⁰. It is well-known that the word problem for the Grigorchuk group is in L
 253 (see e.g. [13, 30]). Thus, also the power word problem is in L.

254 **Proof sketch of Theorem 10.** By [5, Theorem 6.6], every element of length N in the Grig-
 255 orchuk group has order at most $CN^{3/2}$ for some constant C . Since the order of every element
 256 is a power of two, we can reduce all exponents modulo the smallest power of two $\geq CN^{3/2}$
 257 where N is the length of the longest period p_i . After that the words are short and can be
 258 written without exponents. ◀

259 4 Proof of Theorem 2

260 The proof of Theorem 2 consists of two main steps: first we do some preprocessing leading to
 261 a particularly nice instance of the power word problem. While this preprocessing is simple
 262 from a theoretical point of view, it is where the main part of the workload is performed
 263 during the execution of the algorithm. Then, in the second step, all exponents are reduced
 264 to polynomial size. After this shortening process, the power word problem can be solved by
 265 the ordinary word problem. The most difficult part is to prove correctness of the shortening
 266 process. For this, we introduce a rewriting system over an extended alphabet of words with
 267 exponents. We outline the proof in a sequence of lemmas which all follow rather easily from
 268 the previous ones and we give some small hints how to prove the lemmas.

269 **Preprocessing.** We use the notations from the paragraph on free groups in Section 2. In
 270 particular, recall that $S = \{aa^{-1} \rightarrow 1 \mid a \in \Sigma\}$. Fix an arbitrary order on the input
 271 alphabet Σ . This gives us the lexicographic order on Σ^* , which is denoted by \preceq . Let
 272 $\Omega \subseteq \text{IRR}(S) \subseteq \Sigma^*$ denote the set of words w such that

- 273 ■ w is non-empty,
- 274 ■ w is cyclically reduced (i.e, w cannot be written as aua^{-1} for $a \in \Sigma$),
- 275 ■ w is primitive (i.e, w cannot be written as u^n for $n \geq 2$),
- 276 ■ w is lexicographically minimal among all cyclic permutations of w and w^{-1} (i.e., $w \preceq uv$
 277 for all $u, v \in \Sigma^*$ with $vu = w$ or $vu = w^{-1}$).

278 Notice that Ω consists of Lyndon words [29, Chapter 5.1] with the stronger requirement of
 279 being freely reduced, cyclically reduced and also minimal among the conjugacy class of the
 280 inverse. The first aim is to rewrite the input power word in the form

$$281 \quad w = s_0 p_1^{x_1} s_1 \cdots p_n^{x_n} s_n \quad \text{with } p_i \in \Omega \text{ and } s_i \in \text{IRR}(S). \quad (1)$$

283 The reason for this lies in the following crucial lemma which essentially says that, if a long
 284 factor of $p_i^{x_i}$ cancels with some $p_j^{x_j}$, then already $p_i = p_j$. Thus, only the same p_i can cancel
 285 implying that we can make the exponents of the different p_i independently smaller.

286 ► **Lemma 11.** *Let $p, q \in \Omega$, $x, y \in \mathbb{Z}$ and let v be a factor of p^x and w a factor of q^y . If*
 287 *$vw \xrightarrow[S]{*} 1$ and $|v| = |w| \geq |p| + |q| - 1$, then $p = q$.*

23:8 The power word problem

288 **Proof.** Since p and q are cyclically reduced, v and w are freely reduced, i.e., $v = w^{-1}$ as words.
 289 Thus, v has two periods $|p|$ and $|q|$. Since v is long enough, by the theorem of Fine and Wilf
 290 [10] it has also a period of $\gcd(|p|, |q|)$. This means that also p and q have period $\gcd(|p|, |q|)$
 291 (since cyclic permutations of p and q are factors of v). Assuming $\gcd(|p|, |q|) < |p|$, would
 292 mean that p is a proper power contradicting the fact that p is primitive. Hence, $|p| = |q|$.
 293 Since $|v| \geq |p| + |q| - 1 = 2|p| - 1$, p is a factor of v , which itself is a factor of q^{-y} . Thus, p
 294 is a cyclic permutation of q or of q^{-1} . By the last condition on Ω , this implies $p = q$. ◀

295 ► **Lemma 12.** *The following is in $\text{uAC}^0(\text{WP}(F_2))$: given a power word v , compute a power*
 296 *word w of the form (1) such that $v =_{F_X} w$.*

297 The proof of this lemma is straightforward using [40, Proposition 20] in order to compute
 298 freely reduced words. We call these steps the *preprocessing steps*. Henceforth, we will assume
 299 that the inputs for the power word problem are given in the form (1).

300 **The symbolic reduction system.** We define the infinite alphabet $\Delta = \Delta' \cup \Delta''$ with
 301 $\Delta' = \Omega \times (\mathbb{Z} \setminus \{0\})$ and $\Delta'' = \text{IRR}(S) \setminus \{1\}$. We write p^x for $(p, x) \in \Delta'$. A word over Δ can
 302 be read as a word over Σ in the natural way. Formally, we can define a canonical projection
 303 $\pi : \Delta^* \rightarrow \Sigma^*$ that maps a symbol $a \in \Delta$ to the corresponding word over Σ , but most of the
 304 times we will not write π explicitly.

305 Whenever there is the risk of confusion, we write $|v|_\Sigma$ to denote the length of $v \in \Delta^*$
 306 read over Σ (i.e., $|v|_\Sigma = |\pi(v)|$) whereas $|v|_\Delta$ is the length over Δ . Moreover, we denote
 307 the number of occurrences of letters from Δ' in w with $|w|_{\Delta'}$. Finally, for a symbol $s \in \Delta''$
 308 define $\lambda(s) = |s|_\Sigma$ and for $p^x \in \Delta'$ set $\lambda(p^x) = |p|_\Sigma$. For $u = a_1 \cdots a_m \in \Delta^*$ with $a_i \in \Delta$ for
 309 $1 \leq i \leq m$ we define $\lambda(u) = \sum_{i=1}^m \lambda(a_i)$. Thus, $\lambda(u)$ is the number of letters from Σ required
 310 to write down u ignoring the binary exponents.

311 A word w as in (1), which has been preprocessed as in the previous section, can be viewed
 312 as word over Δ with $w \in ((\Delta'' \cup \{1\})\Delta')^*(\Delta'' \cup \{1\})$, $|w|_{\Delta'} = n$ and $|w|_\Delta \leq 2n + 1$ (we only
 313 have \leq because some s_i might be empty).

314 We define the infinite string rewriting system T over Δ^* by the following rewrite rules,
 315 where $p^x, p^y, q^y \in \Delta'$, $s, t \in \Delta''$, $r \in \Delta'' \cup \{1\}$, and $d, e \in \mathbb{Z}$. Here, p^0 is identified with the
 316 empty word. Note that the strings in the rewrite rules are over the alphabet Δ , whereas the
 317 strings in the if-conditions are over the alphabet Σ .

$$318 \quad p^x p^y \rightarrow p^{x+y} \quad (2)$$

$$319 \quad p^x q^y \rightarrow p^{x-d} r q^{y-e} \quad \text{if } p \neq q, p^x q^y \xrightarrow{+}_S p^{x-d} r q^{y-e} \in \text{IRR}(S) \text{ for} \quad (3)$$

$$320 \quad r = p' q' \text{ with } p' <_{\text{pref}} p^{\text{sign}(x)} \text{ and } q' <_{\text{suff}} q^{\text{sign}(y)}$$

$$321 \quad st \rightarrow r \quad \text{if } st \xrightarrow{+}_S r \in \text{IRR}(S) \quad (4)$$

$$322 \quad p^x s \rightarrow p^{x-d} r \quad \text{if } p^x s \xrightarrow{+}_S p^{x-d} r \in \text{IRR}(S) \text{ for} \quad (5)$$

$$323 \quad r = p' s' \text{ with } p' <_{\text{pref}} p^{\text{sign}(x)} \text{ and } s' <_{\text{suff}} s$$

$$324 \quad sp^x \rightarrow rp^{x-d} \quad \text{if } sp^x \xrightarrow{+}_S rp^{x-d} \in \text{IRR}(S) \text{ for} \quad (6)$$

$$325 \quad r = s' p' \text{ with } s' <_{\text{pref}} s \text{ and } p' <_{\text{suff}} p^{\text{sign}(x)}$$

326
 327 ► **Lemma 13.** *The following length bounds hold in the above rules:*

328 ■ *in rule (3): $0 < |r|_\Sigma \leq |p|_\Sigma + |q|_\Sigma$, $|d| \leq |q|_\Sigma$, and $|e| \leq |p|_\Sigma$*

329 ■ *in rules (5) and (6): $|d| \leq |s|_\Sigma$.*

330 The inequalities $|d| \leq |q|_\Sigma$ and $|e| \leq |p|_\Sigma$ follow from Lemma 11. The other inequalities are
 331 obvious. The next lemma is also straightforward from the definition.

332 ► **Lemma 14.** For $u \in \Delta^*$ we have $u =_{F_X} 1$ if and only if $u \xrightarrow{T^*} 1$.

333 ► **Lemma 15.** Let $u \in \Delta^*$. If $u \xrightarrow{T^*} v$, then $u \xrightarrow{T^{\leq k}} v$ for $k = 2|u|_{\Delta'} + 4|u|_{\Delta} \leq 6|u|_{\Delta}$.

334 **Proof sketch.** The proof is based on the fact that at most $2|u|_{\Delta'} - 3$ applications of rules of
 335 the form (3) can occur. These are the only length increasing rules. All other rules either
 336 decrease the number of non-reduced two-letter factors of u (this can happen at most $|u|_{\Delta} - 1$
 337 times) or decrease the length of u (this can happen at most $|u|_{\Delta} + 2|u|_{\Delta'} - 3$ times). ◀

338 Consider a word $u \in \Delta^*$ and $p \in \Omega$. Let $\Delta_p = \{p^x \mid x \in \mathbb{Z} \setminus \{0\}\}$. We can write u
 339 uniquely as $u = u_0 p^{y_1} u_1 \cdots p^{y_m} u_m$ with $u_i \in (\Delta \setminus \Delta_p)^*$. We define $\eta_p^i(u) = \sum_{j=1}^i y_j$ and
 340 $\eta_p(u) = \eta_p^m(u)$. By Lemma 13 we know that all rules of T change $\eta_p(\cdot)$ by at most $\lambda(u)$. We
 341 can use this observation in order to show the next lemma by induction on k .

342 ► **Lemma 16.** Let $u \xrightarrow{T^k} v$. Then for all $v' \leq_{\text{pref}} v$ with $v' \in \Delta^*$ there is some $u' \in \Delta^*$ with
 343 $u' \leq_{\text{pref}} u$ and $|\eta_p(u') - \eta_p(v')| \leq (k+1)^2 \lambda(u)$.

344 **The shortened version of a word.** Take a word $u \in \Delta^*$ and $p \in \Omega$ and write u as
 345 $u = u_0 p^{y_1} u_1 \cdots p^{y_m} u_m$ with $u_i \in (\Delta \setminus \Delta_p)^*$ (we are only interested in the case that p^x
 346 appears as a letter in u for some $x \in \mathbb{Z}$). Let \mathcal{C} be a finite set of finite, non-empty, non-
 347 overlapping intervals of integers, i.e., we can write $\mathcal{C} = \{[\ell_j, r_j] \mid 1 \leq j \leq k\}$ for $k = |\mathcal{C}|$ and
 348 $\ell_j \leq r_j$ for all j . We can assume that the intervals are ordered increasingly, i.e., we have
 349 $r_j < \ell_{j+1}$. We set $d_j = r_j - \ell_j + 1 > 0$. We say that u is *compatible* with \mathcal{C} if $\eta_p^i(u) \notin [\ell_j, r_j]$
 350 for any i, j . If w is compatible with \mathcal{C} , we define the *shortened version* $\mathcal{S}_{\mathcal{C}}(u)$ of u : for
 351 $i \in \{1, \dots, m\}$ we set

$$352 \quad C_i = C_i(u) = \begin{cases} \{j \mid 1 \leq j \leq k, \eta_p^{i-1}(u) < \ell_j \leq r_j < \eta_p^i(u)\} & \text{if } y_i > 0 \\ \{j \mid 1 \leq j \leq k, \eta_p^i(u) < \ell_j \leq r_j < \eta_p^{i-1}(u)\} & \text{if } y_i < 0, \end{cases}$$

353 i.e., C_i collects all intervals between $\eta_p^{i-1}(u)$ and $\eta_p^i(u)$. Then $\mathcal{S}_{\mathcal{C}}(u)$ is defined by

$$354 \quad \mathcal{S}_{\mathcal{C}}(u) = u_0 p^{z_1} u_1 \cdots p^{z_m} u_m \quad \text{where} \\ 355 \quad z_i = y_i - \text{sign}(y_i) \cdot \sum_{j \in C_i} d_j = \begin{cases} y_i - \sum_{j \in C_i} d_j & \text{if } y_i > 0, \\ y_i + \sum_{j \in C_i} d_j & \text{if } y_i < 0. \end{cases} \\ 356$$

357 A straightforward computation yields the next lemma:

358 ► **Lemma 17.** For all i we have $z_i \neq 0$ and $\text{sign}(z_i) = \text{sign}(y_i)$. In particular, if $u \in \text{IRR}(T)$,
 359 then also $\mathcal{S}_{\mathcal{C}}(u) \in \text{IRR}(T)$.

360 Furthermore, we define $\text{dist}_p(u, \mathcal{C}) = \min \{ |\eta_p^i(u) - x| \mid 0 \leq i \leq m, x \in [\ell, r] \in \mathcal{C} \}$. Note
 361 that $\text{dist}_p(u, \mathcal{C}) > 0$ if and only if u is compatible with \mathcal{C} . Moreover, if $\text{dist}_p(u, \mathcal{C}) = a$,
 362 $v = v_0 p^{z_1} v_1 \cdots p^{z_m} v_m$, and $|\eta_p^i(u) - \eta_p^i(v)| \leq b$ for all $i \leq m$, then $\text{dist}_p(v, \mathcal{C}) \geq a - b$.

363 ► **Lemma 18.** If $\text{dist}_p(u, \mathcal{C}) > (k+1)^2 \lambda(u)$ and $u \xrightarrow{T^k} v$, then $\mathcal{S}_{\mathcal{C}}(u) \xrightarrow{T^k} \mathcal{S}_{\mathcal{C}}(v)$.

23:10 The power word problem

■ **Figure 1** The red shaded parts represent the intervals from the set $\mathcal{C}_{u,p}^K$ in (7). The differences $c_3 - c_2$, $c_6 - c_5$, $c_7 - c_6$ and $c_9 - c_8$ are strictly smaller than $2K$.

364 **Proof sketch.** The first step for proving this lemma is to show that if $\text{dist}_p(u, \mathcal{C}) > \lambda(u)$ and
 365 $u \xrightarrow{T} v$, then $S_{\mathcal{C}}(u) \xrightarrow{T} S_{\mathcal{C}}(v)$. To see this this, we distinguish between the rules applied:
 366 When applying one of the rules (3)–(6), we have $C_i(u) = C_i(v)$ for all i since the exponents
 367 are only changed slightly. Thus, the shortening process does the same on v as on u . When
 368 applying a rule (2), the exponents are added, which is compatible with the shortening process.
 369 Now we obtain the lemma by induction on k . In order to see that $\text{dist}_p(u, \mathcal{C}) > \lambda(u)$ is
 370 satisfied in the inductive step, we use Lemma 16. ◀

371 We define a set of intervals which should be “cut out” from u as follows: We write
 372 $\{c_1, \dots, c_l\} = \{\eta_p^i(u) \mid 0 \leq i \leq m\}$ with $c_1 < \dots < c_l$ and we set

$$373 \quad \mathcal{C}_{u,p}^K = \{[c_j + K, c_{j+1} - K] \mid 1 \leq j \leq l - 1, c_{j+1} - c_j \geq 2K\}. \quad (7)$$

374 Notice that $\text{dist}_p(u, \mathcal{C}_{u,p}^K) = K$ (given that $\mathcal{C}_{u,p}^K \neq \emptyset$). The situation is shown in Figure 1.

375 ► **Proposition 19.** Let $p \in \Omega$, $u = u_0 p^{y_1} u_1 \dots p^{y_m} u_m \in \Delta^*$ with $u_i \in (\Delta \setminus \Delta_p)^*$, and
 376 $K = (6|u|_{\Delta} + 1)^2 \lambda(u) + 1$. Then $u =_{F_X} 1$ if and only if $S_{\mathcal{C}}(u) =_{F_X} 1$ for $\mathcal{C} = \mathcal{C}_{u,p}^K$.

377 **Proof.** By Lemma 14 we have $u =_{F_X} 1$ if and only if $u \xrightarrow{T^*} 1$. Let $k = 6|u|_{\Delta}$. By Lemma 15,
 378 for all $u \xrightarrow{T^*} v$ we have $u \xrightarrow{\leq k} v$. By the choice of \mathcal{C} , we have $\text{dist}_p(u, \mathcal{C}) > (k + 1)^2 \lambda(u)$.
 379 Hence, we can apply Lemma 18, which implies that $S_{\mathcal{C}}(u) \xrightarrow{T^*} S_{\mathcal{C}}(v)$ where v is a T -reduced
 380 (thus freely reduced) word for u . Clearly, if v is the empty word, then $S_{\mathcal{C}}(v)$ will be the
 381 empty word. On the other hand, if v is non-empty, then $S_{\mathcal{C}}(v)$ is non-empty and T -reduced
 382 by Lemma 17. Hence, we have $u =_{F_X} 1$ if and only if $S_{\mathcal{C}}(u) =_{F_X} 1$. ◀

383 ► **Lemma 20.** Let p, u, K , and \mathcal{C} be as in Proposition 19 and $S_{\mathcal{C}}(u) = u_0 p^{z_1} u_1 \dots p^{z_m} u_m$.
 384 Then $|z_i| \leq m \cdot (2 \cdot (6|u|_{\Delta} + 1)^2 \cdot \lambda(u) + 1)$ for all $1 \leq i \leq m$.

385 **Proof of Theorem 2.** We start with the preprocessing as described in Lemma 12 leading to
 386 a word $w = s_0 p_1^{x_1} s_1 \cdots p_n^{x_n} s_n$ with $p_i \in \Omega$ and $s_i \in \text{IRR}(S)$ as in (1). After that we apply
 387 the shortening procedure for all $p \in \{p_i \mid 1 \leq i \leq n\}$. This can be done in parallel for all p ,
 388 as the outcome of the shortening only depends on the p -exponents. By Lemma 20 this leads
 389 to a word \hat{w} of polynomial length. Finally, we can test whether $\hat{w} =_{F_X} 1$ using one oracle
 390 gate for $\text{WP}(F_2)$ (recall that F_2 contains a copy of F_X). The computations for shortening
 391 only involve iterated addition (and comparisons of integers), which is in uTC^0 and, thus, can
 392 be solved in uAC^0 with oracle gates for $\text{WP}(F_2)$. ◀

393 5 The power word problem in wreath products

394 The goal of this section is to prove Theorems 8 and 9. We first fix some notation. Let G
 395 be a finitely generated group with the finite symmetric generating set Σ . For \mathbb{Z} we fix the
 396 generator a . Hence $\Sigma \cup \{a, a^{-1}\}$ is a symmetric generating set for the wreath product $G \wr \mathbb{Z}$.
 397 For a word $w = v_0 a^{e_1} v_1 \cdots a^{e_n} v_n$ with $e_i \in \{-1, 1\}$ and $v_i \in \Sigma^*$ let $\sigma(w) = e_1 + \cdots + e_n$.
 398 With $I(w)$ we denote the interval $[b, c] \subseteq \mathbb{Z}$, where b (resp., c) is the minimal (resp., maximal)
 399 integer of the form $e_1 + \cdots + e_i$ for $0 \leq i \leq n$. Note that if w represents $(f, d) \in G \wr \mathbb{Z}$, then
 400 $d = \sigma(w)$, $\text{supp}(f) \subseteq I(w)$ and $0, d \in I(w)$.

401 **Periodic words over groups.** We recall a construction from [12]. With G^+ we denote
 402 the set of all tuples (g_0, \dots, g_{q-1}) over G of arbitrary length $q \geq 1$. With G^ω we denote
 403 the set of all mappings $f : \mathbb{N} \rightarrow G$. Elements of G^ω can be seen as infinite sequences (or
 404 words) over the set G . We define the binary operation \otimes on G^ω by pointwise multiplication:
 405 $(f \otimes g)(n) = f(n)g(n)$. The identity element is the mapping id with $\text{id}(n) = 1$ for all $n \in \mathbb{N}$.
 406 For $f_1, f_2, \dots, f_n \in G^\omega$ we write $\bigotimes_{i=1}^n f_i$ for $f_1 \otimes f_2 \otimes \cdots \otimes f_n$. If G is abelian, we write
 407 $\sum_{i=1}^n f_i$ for $\bigotimes_{i=1}^n f_i$. A function $f \in G^\omega$ is periodic with period $q \geq 1$ if $f(k) = f(k+q)$ for
 408 all $k \geq 0$. In this case, f can be specified by the tuple $(f(0), \dots, f(q-1))$. Vice versa, a tuple
 409 $u = (g_0, \dots, g_{q-1}) \in G^+$ defines the periodic function $f_u \in G^\omega$ with $f_u(n \cdot q + r) = g_r$ for
 410 $n \geq 0$ and $0 \leq r < q$. One can view this mapping as the sequence u^ω obtained by taking
 411 infinitely many repetitions of u . Let G^ρ be the set of all periodic functions from G^ω . If f_1
 412 is periodic with period q_1 and f_2 is periodic with period q_2 , then $f_1 \otimes f_2$ is periodic with
 413 period $q_1 q_2$ (in fact, $\text{lcm}(q_1, q_2)$). Hence, G^ρ forms a countable subgroup of G^ω . Note that
 414 G^ρ is not finitely generated: The subgroup generated by elements $f_i \in G^\rho$ with period q_i
 415 ($1 \leq i \leq n$) contains only functions with period $\text{lcm}(q_1, \dots, q_n)$. For $n \geq 0$ we define the
 416 subgroup G_n^ρ of all $f \in G^\rho$ with $f(k) = 1$ for all $0 \leq k \leq n-1$. We consider the uniform
 417 membership problem for subgroups G_n^ρ , $\text{MEMBERSHIP}(G_n^\rho)$ for short:

- 418 ■ input: tuples $u_1, \dots, u_n \in G^+$ (elements of G are represented by finite words over Σ) and
 419 a binary encoded number m .
- 420 ■ question: does $\bigotimes_{i=1}^n f_{u_i}$ belong to G_m^ρ ?

421 The following result was shown in [12]:

422 ▶ **Theorem 21.** For every finitely generated abelian group G , $\text{MEMBERSHIP}(G_n^\rho)$ is in uTC^0 .

423 ▶ **Lemma 22.** Let $w \in (\Sigma \cup \{a, a^{-1}\})^*$ with $\sigma(w) \neq 0$, $n \geq 1$, and $I(w^n) = [b, c]$. Moreover,
 424 let $s = c - b + 1$ be the size of the interval $I(w)$ and let $(g, n \cdot \sigma(w)) \in G \wr \mathbb{Z}$ be the group
 425 element represented by w^n . Then g is periodic on the interval $[b+s, c-s]$ with period $|\sigma(w)|$.

426 ▶ **Example 23.** Let us consider the wreath product $\mathbb{Z} \wr \mathbb{Z}$ and let the left copy of \mathbb{Z} in the
 427 wreath product be generated by b . Consider the word $w = ba^{-1}babab^3ab^3ab^5a^{-1}b$ and let
 428 $n = 8$. We have $\sigma(w) = 2$ and $I(w) = [-1, 3]$. Moreover, w represents the group element

23:12 The power word problem

429 $(f, 2)$ with $f(-1) = 1, f(0) = 2, f(1) = 3, f(2) = 4,$ and $f(3) = 5$. Let us now consider the
 430 word w^8 . The following diagram shows how to obtain the corresponding element of $\mathbb{Z} \wr \mathbb{Z}$:

	-1	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17
	1	2	3	4	5														
			1	2	3	4	5												
431					1	2	3	4	5										
							1	2	3	4	5								
										1	2	3	4	5					
												1	2	3	4	5			
														1	2	3	4	5	
	1	2	4	6	9	6	9	6	9	6	9	6	9	6	9	6	8	4	5

432 We have $I(w^8) = [-1, 17]$ and $\sigma(w^8) = 8\sigma(w) = 16$. If $(g, 16)$ is the group element represented
 433 by w^8 , then the function g is periodic on the interval $[2, 14]$ (which includes the interval
 434 $[-1 + s, 17 - s]$, where $s = |I(w)| = 5$) with period 2.

435 **Proofs of Theorem 8 and 9.** A conjunctive truth-table reduction is a Turing reduction
 436 where the output is the conjunction over the outputs of all oracle gates.

437 **► Proposition 24.** *For every finitely generated group G , $\text{POWERWP}(G \wr \mathbb{Z})$ is conjunctive*
 438 *truth-table uTC^0 -reducible to $\text{MEMBERSHIP}(G_*^p)$ and $\text{POWERWP}(G)$.*

439 **Proof sketch.** Let $w = u_1^{x_1} u_2^{x_2} \dots u_k^{x_k}$ be the input power word and let $(f, d) \in G \wr \mathbb{Z}$ be the
 440 element represented by w . We can check in uTC^0 whether $d = 0$. The difficult part is to
 441 check whether f is the zero-mapping. For this we compute an interval I (of exponential size)
 442 that contains the support of f . We then partition I into two sets C and $I \setminus C$. The set C has
 443 polynomial size and we can check whether f is the zero-mapping on C using polynomially
 444 many oracle calls to $\text{POWERWP}(G)$. The complement $I \setminus C$ can be written as a union of
 445 polynomially many intervals. The crucial property of C is that on each of these intervals f
 446 can be written as a sum of periodic sequences; for this we use Lemma 22. Using oracle calls
 447 to $\text{MEMBERSHIP}(G_*^p)$ allows us to check whether f is the zero mapping on $I \setminus C$. ◀

448 Since for a finitely generated abelian group G , one can solve $\text{POWERWP}(G)$ in uTC^0 ,
 449 Theorem 8 is a consequence of Proposition 24 and Theorem 21.

450 We split the proof of Theorem 9 into three propositions: one for the upper bound and
 451 two for the lower bounds. It is straightforward to show that if the word problem for the
 452 finitely generated group G belongs to coNP , then also $\text{MEMBERSHIP}(G_*^p)$ belongs to coNP .
 453 Since coNP is closed under conjunctive truth-table uTC^0 -reducibility, Proposition 24 yields:

454 **► Proposition 25.** *Let G be a finitely generated group such that $\text{POWERWP}(G)$ belongs to*
 455 *coNP . Then also $\text{POWERWP}(G \wr \mathbb{Z})$ belongs to coNP .*

456 **► Proposition 26.** *If G is a finite, non-solvable group, $\text{POWERWP}(G \wr \mathbb{Z})$ is coNP -hard.*

457 **Proof sketch.** Barrington [4] proved the following result: Let C be a fan-in two boolean
 458 circuit of depth d with n input gates x_1, \dots, x_n . From C one can compute a sequence of
 459 triples (a so-called G -program) $P_C = (k_1, g_1, h_1)(k_2, g_2, h_2) \dots (k_\ell, g_\ell, h_\ell) \in ([1, n] \times G \times G)^*$
 460 of length $\ell \leq (4|G|)^d$ such that for every input valuation $v : \{x_1, \dots, x_n\} \rightarrow \{0, 1\}$ the
 461 following two statements are equivalent:

462 (a) C evaluates to 0 under the input valuation v .

463 (b) $c_1 c_2 \cdots c_\ell = 1$ in G , where $c_i = g_i$ if $v(x_{k_i}) = 0$ and $c_i = h_i$ if $v(x_{k_i}) = 1$.
 464 This G -program is constructed as a sequence of iterated commutators, based on the observa-
 465 tion that $[g, h] = 1$ if and only if $g = 1$ or $h = 1$ (given some reasonable assumptions on g
 466 and h). Every formula C in conjunctive normal form can be written as a circuit of depth
 467 $\mathcal{O}(\log |C|)$. Hence the G -program P_C has length polynomial in $|C|$. From [4] it is easy to see
 468 that on input of the formula C , the G -program P_C can be computed in logspace.

469 Let $P_C = (k_1, g_1, h_1) \cdots (k_\ell, g_\ell, h_\ell)$ and x_1, \dots, x_n be the variables in C . We compute
 470 in logspace the n first primes p_1, \dots, p_n and $M = \prod_{i=1}^n p_i$ (the latter in binary notation).
 471 Let a denote the generator of \mathbb{Z} in the wreath product $G \wr \mathbb{Z}$. We now compute for every
 472 $1 \leq i \leq \ell$ the power word $w_i = (h_i (a g_i)^{p_{k_i} - 1} a)^{M/p_{k_i}} a^{-M}$ and set $w_C = w_1 w_2 \cdots w_\ell$. The
 473 group element of $G \wr \mathbb{Z}$ represented by w_C is of the form $(f, 0)$.

474 We claim that $w_C = 1$ in $G \wr \mathbb{Z}$ if and only if C is unsatisfiable: For a number $z \in [0, M - 1]$
 475 we define the valuation $v_z : \{x_1, \dots, x_n\} \rightarrow \{0, 1\}$ by $v_z(x_i) = 1$ if $z \equiv 0 \pmod{p_i}$ and $v_z(x_i) =$
 476 0 otherwise. By the Chinese remainder theorem, for every valuation $v : \{x_1, \dots, x_n\} \rightarrow \{0, 1\}$
 477 there exists $z \in [0, M - 1]$ with $v = v_z$. Based on the above statements (a) and (b), the final
 478 step of the proof checks that $f(z) = 1$ if and only if C evaluates to 0 under v_z . ◀

479 ▶ **Proposition 27.** *Let F be a finitely generated free group of rank at least two. Then*
 480 *POWERWP($F \wr \mathbb{Z}$) is coNP-hard.*

481 The proof is almost the same as for Proposition 26. The difference is that we mimic Robinson's
 482 proof that the word problem for F_2 is NC^1 -hard [36] instead of Barrington's result.

483 6 Further Research

484 We conjecture that the method of Section 4 can be generalized to right-angled Artin groups
 485 (RAAGs – also known as graph groups) and hyperbolic groups, and hence that the power word
 486 problem for a RAAG (resp., hyperbolic group) G is AC^0 -Turing-reducible to the word problem
 487 for G . One may also try to prove transfer results for the power word problem with respect
 488 to group theoretical constructions, e.g., graph products, HNN extensions and amalgamated
 489 products over finite subgroups. For finitely generated linear groups, the power word problem
 490 leads to the problem of computing matrix powers with binary encoded exponents. The
 491 complexity of this problem is open; variants of this problem have been studied in [1, 11].

492 Another open question is what happens if we allow nested exponents. We conjecture
 493 that in the free group for any nesting depth bounded by a constant the problem is still in
 494 $\text{uAC}^0(\text{WP}(F_2))$. However, for unbounded nesting depth it is not clear what happens: we
 495 only know that it is in P since it is a special case of the compressed word problem; but it
 496 still could be in $\text{uAC}^0(\text{WP}(F_2))$ or it could be P -complete or somewhere in between.
